Hepatitis C virus (HCV) is a major causative agent of chronic liver disease worldwide. Although antiviral therapy with interferon-based regimens is highly effective, some patients are resistant to its treatment. It is therefore imperative to identify new targets and agents for the treatment of hepatitis C. The 3' untranslated region (UTR) of the HCV genome has a highly conserved stem-loop structure known as the internal ribosome entry site (IRES). This stem-loop structure of the HCV 3'UTR contains the essential cis-acting elements required for the translation of the viral polyprotein. HCV IRES consists of multiple stem-loops. It has been suggested that the HCV core protein is the RNA-binding protein that recognizes and binds the HCV IRES. We have constructed a recombinant plasmid carrying the siRNA complementary to the core protein gene. Using the recombinant plasmid, we transfected it into the human hepatoma cell line, Huh7, and performed luciferase assay. We demonstrated that the siRNA-mediated silencing of the HCV core protein resulted in significant down-regulation of the HCV replication in transfected Huh7 cells, and these results were confirmed by northern blotting. Taken together, our findings indicate that siRNA-mediated silencing of the HCV core protein may be a1d647c40b
