The evolution of flower morphology is often seen as the advent of sex or as a means of solving the problem of self-fertilization. In flowering plants, however, flowers and sex are co-opted from their original function in ovule production and pollen dispersal. The zygomorphy of flowers is believed to stem from self-fertilization in their insect pollination mutualisms. The result of this co-option, however, is a remarkable resemblance among plants that otherwise differ greatly in their pollination, and this has attracted scientists from a wide variety of disciplines. The answer to the question of why flowers are zygomorphic may lie in the ease of understanding their development, such as the constrained organization of flowers into an ovule that includes the ovary, pistil and stamen. // Copyright Aleksey Gurtovoy 2000-2004 // // Distributed under the Boost Software License, Version 1.0. // (See accompanying file LICENSE_1_0.txt or copy at //
