Port Forward is a Windows Service that forwards any arbitrary set of local port to any other port, local or remote. Port Forward calls a Windows Service that forwards any arbitrary set of local ports to any other set of ports, local or remote. Port Forward is designed to avoid security risks associated with services that listen on a single IP address or accept a list of IP addresses. Port Forward does not accept IP addresses as part of its configuration. You can use the same Port Forward service port on multiple hosts by configuring the service to listen on any set of IP addresses. AT Port Forward Security Problem: Connecting directly to services on the Internet can be dangerous. The service may be compromised, and hackers may use the service to launch attacks on your network or serve up malicious files that you downloaded. For example, someone may steal your credit card numbers and use them for illegal purposes. It is possible to reduce your exposure to these risks by using a security model that separates the design of a network service from the way in which it is implemented. This way, a firewall on your network or a network segment may prevent hackers from directly attacking a service. At the same time, the service does not have to be able to accept direct connections.
