The results of this analysis lead to several conclusions. Firstly, the number of infected nodes required to generate a large number of cascades is small. We found that to generate 10^6 infections, only a few hundreds of infected nodes are required. Secondly, the viral infection behaviour is very similar to the SIR model (Fig. 2). This means that the distribution of viruses is roughly proportional to the distribution of infected nodes. Thirdly, our model is based on a simple degree distribution which is usually observed in real networks, and it is not necessary to extend our model to consider the correlation between node degrees. We also investigated the effect of initial conditions in a short time window, i.e. we sampled several time windows after the start of the virus spreading process and analysed the distribution of
