You can access the most common commands for the drawing type you’re working on, by clicking on the + sign on the right side of the navigation bar. As is well known in the railroad industry, a snowplow is an implement which is utilized for clearing snow and the like from the tracks of a railroad. Snowplows can be mounted on either the locomotive or the cars of a train. There are several types of snowplows that have been developed. One type of snowplow is a full width snowplow which is typically mounted on the locomotive. A full width snowplow plows across the full width of the tracks in front of the locomotive, which is the direction that the train is traveling. In order to effectively plow a wider area, two or more snowplows can be mounted on the locomotive. Another type of snowplow is a wide angle snowplow. A wide angle snowplow typically includes a snowplow body, a pair of plow arms pivotally attached to the snowplow body and extending outwardly therefrom. One of the plow arms is moveable relative to the other plow arm to adjust the effective width of the snowplow. Another type of snowplow is a dump type snowplow. A dump type snowplow has an elongate body with a hinge. The hinge is positioned at a front end of the snowplow body. A front plow blade is pivotally mounted to the snowplow body. When the snowplow body is moved rearwardly about the hinge, the front plow blade is pivoted upwardly toward a generally vertical position to facilitate the snowplowing operation. A snowplow can also be a push type snowplow. A push type snowplow includes a tractor vehicle that is typically drawn behind a locomotive. The tractor vehicle includes a body, a pair of push arms pivotally attached to the body, and a plow blade attached to the pair of push arms. A pair of pneumatic cylinders are connected to the body and the pair of push arms, and can be used to move the body and push arms relative to each other. By actuating the pneumatic cylinders, the push arms and plow blade can be pivoted upwardly and downwardly.
